Brief Introduction to the classic multiplication algorithm

Normal Divide And conquer Algorithm

**03** Karatsuba Algorithm

Asymptotic Time Complexity

### **Classic Multiplication Algorithm**

```
The classical algorithm:
Input: N-digits integer X and Y
   for ( int i = 1; i <= n; i++){
                for( int j = 1; j <= n; j + +)
                balabala...
不妨定义计算复杂度的基本操作:
        single-digit products cost: O(1)
        single-digits addition cost: O(1)
        n-digits addition cost : O(n)
        n-digits shift operation cost : O(n)
n^2 single-digit products.
大约 n^2 single-digit addition.
即总的时间开销为O(n²)
```

## Normal Divide And Conquer Algorithm

Input: n-digits integer X and Y

将X,Y按位数均分成为两部分,可得 $x_0,x_1y_0,y_1$ 关系如下:

$$X = x_0 \cdot 10^m + x_1$$
;  
 $Y = y_0 \cdot 10^m + y_1$ ; (m = n/2)

那么:  $XY = (x_0 \cdot 10^m + x_1) (y_0 \cdot 10^m + y_1) = x_0 y_0 10^{2m} + 10^m (x_0 y_1 + x_1 y_0) + x_1 y_1$ 么问题即变为求上述的对应 $x_0 y_0$ , $x_0 y_1$ , $x_1 y_0$ , $x_1 y_1$  4次规模为n/2的乘法以及一些加法操作和移位操作。

#### 算法的时间开销分析:

$$T(n) = 4T(n/2) + cn + d$$

根据 master theorem 的 case1:

$$\mathsf{T}(\mathsf{n}) = O(n^{log4}) = O(n^2)$$

#### Improvement of the normal divideand-conquer algorithm

Andrey Kolmogorov(安德雷·柯尔莫哥洛夫)(俄国-概率论公理化)
conjectured the classic multiplication algorithm asymptotically optimal.

通过对算法复杂度递归式的分析:

复杂度没有降低的本质原因出在分治后仍然要进行4次乘法上。

In 1960, Karatsuba, a 23-year-old student, multiplies two *n*-digit numbers in  $\Theta(n^{\log_2 3})$  elementary steps.

#### Karatsuba algorithm

The basic step of Karatsuba 's algorithm is a formula that allows one to compute the product of two large numbers X and Y using three multiplications of smaller numbers, each with about half as many digits as X or Y, plus some additions and digit shifts.

<mark>将位数很多的</mark>两个大数X和Y分成位数较少的数,每个数都是原来X和Y位数的一半。这样处理之后,简化 为做三次乘法,并附带少量的加法操作和移位操作。

即相比于标准的分治递归求解法 算法的重点在于: 将子问题中的四次乘法化为三

将子问题中的四次乘法化为三次乘法

#### Introduction of Karatsuba algorithm

解释:令待处理的大数为X和Y,

解首先将X,Y分别拆开成为两部分,可得 $x_0,x_1y_0,y_1$ 关系如下:

$$X = x_0 \cdot 10^m + x_1;$$
  
 $Y = y_0 \cdot 10^m + y_1;$ 

那么:  $XY = (x_0 \cdot 10^m + x_1) (y_0 \cdot 10^m + y_1) = x_0 y_0 10^{2m} + 10^m (x_0 y_1 + x_1 y_0) + x_1 y_1$  将上述的 4 次乘法转化为 3 次:

$$x_0y_1 + x_1y_0 = (x_0 + x_1) (y_0 + y_1) - x_0y_0 - x_1y_1$$

#### Introduction of Karatsuba algorithm

#### 伪代码:

## **Asymptotic Time Complexity**

$$T(n) = 3T(\lceil n/2 
ceil) + cn + d$$

由 master theorem 的第一种情况知

$$T(n) = \Theta(n^{\log_2 3})$$
 .
